

Typical values for allowable surface pressures for different materials

The limit pressure per unit area should not be exceeded when tightening the screw or the nut otherwise the threaded connection can loosen as a result of seating effects.

Based on VDI 2230, 1986 edition, with proven limiting values

The values given apply to holes without chamfers and with sufficiently large external diameter for the tensioned part at room temperature.

^{a)} *Italic* numerical values: Not yet tested according to the method in [53] or in [64]. Recommendation for steels by using the Brinell hardness: $\rho_G \approx 3 \text{ HB}$

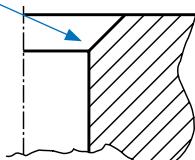

^{b)} According to the method in [64]

Note: All numerical values are short-term values at room temperature and have to be considered as guide values. In the specific instance it may come to deviations due to a large number of influencing factors (geometry, relaxation, etc.).

[Values in parentheses] see literature reference VDI 2230

4) Boundary conditions which affect the surface pressure

Chamfer

Chamfers at the hole (contact surfaces with the fastening element) can for steels result in permitted values for surface pressure up to 25 % higher being achieved (supporting effect).

Power-operated screw-driver

When tightening using a power screwdriver, for steels the permissible limiting value of surface pressure can be up to 25 % lower!

¹⁾ If an indentation is not permissible, i.e. only the surface roughness can be leveled, the surface pressure must not lead to the offset yield strength being exceeded in all operating conditions. In this case, it is recommended to use a maximum of 70 % of the table reference value. This will be printed in the next edition of VDI 2230 under Table A9 along with other additional information.

¹⁾ The values shown in the tables for surface pressure are for a 90 % utilisation of the yield strength of the screw $R_{p,0,2}$ and $\mu_G = 0,12$ (reference: VDI 2230, edition 2015)

Surface pressure under the screw head

It is not possible to precisely define the permissible surface pressure for a particular type of material used to make a component. The effect of the production process, the alignment of fibers in the material, surface finishing and temperature changes all play a decisive role.

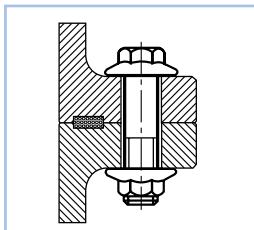

The following measures can help reduce the surface pressure:

- use of flange screws and flange nuts.
- chamfered holes. Field investigations have shown up to a 20% increase in permissible surface pressure.
- through hole to ISO 273 – select a fine hole.

Advantages of flange screws and flange nuts:

- less intrusion.
- clamping force in the fastening during mounting tends to remain stable.
- flange products are more economic than large washers under normal screws and nuts (fewer fastening elements and quicker assembly).
- flange screws and nuts allow greater hole tolerances and so are more economically efficient.
- flange nuts have a better stability against shaking than normal screws and nuts.

Typical application

Surface pressure when mounted

Guide to the use of flat washers for screws and nuts

according to ISO 887

An overview of suitable combinations of flat washers with screws and nuts, allowing for different property classes (hardness classes).

Limiting conditions such as strength of component, surface structure, production process, alignment of fibers and operating temperatures must be considered when making the selection.

Screws Property class	Nuts Property class	Use of washers with corresponding hardness permitted		
		Washers – hardness class and assigned tensile strength [N/mm ²] acc. ISO 18265		
		100 HV 320	200 HV 640	300 HV 965
		Permitted reference values pressure per unit area [N/mm ²]		
		200–300	300–500	500–800
Case-hardened, thread-forming screws	yes	yes	yes	yes
Stainless steel, screws and nuts	—	yes	—	—
≤ 6.8	≤ 6	yes	yes	yes
8.8	8	no	yes	yes
9.8	9	no	no	yes
10.9	10	no	no	yes
12.9	12	no	no	no

Guide to the use of flat washers for screws and nuts for austenitic stainless steel

Recommendation without reference to standards
